Exercise training provokes widespread transformations in the human body, requiring coordinated changes in muscle composition, blood flow, neuronal and hormonal signaling, and metabolism. These changes enhance physical performance, improve mental health, and delay the onset of aging and disease. Understanding the molecular basis of these changes is therefore

important for optimizing athletic ability and for developing drugs that elicit therapeutic effects. Written and edited by experts in the field, this collection from Cold Spring Harbor Perspectives in Medicine examines the biological basis of exercise from the molecular to the systemic levels. Contributors discuss how transcriptional regulation, cytokine and hormonal signaling, glucose metabolism, epigenetic modifications, microRNA profiles, and mitochondrial and ribosomal functions are altered in response to exercise training, leading to improved skeletal muscle, hippocampal, and cardiovascular function. Cross talk among the pathways underlying tissue-specific and systemic

responses to exercise is also considered. The authors also discuss how the understanding of such molecular mechanisms may lead to the development of drugs that mitigate aging and disease. This volume will therefore serve as a vital reference for all involved in the fields of sports science and medicine, as well as anyone seeking to understand the molecular mechanisms by which exercise promotes whole-body health.

Chemotactic Cytokines

The Cytokine Handbook

Human and Social Biology for CSEC Examinations

The existence of a new family of chemotactic cytokines was realised in 1987 following the isolation and structural determination by several groups of a peptide consisting of 72 amino acids which was a potent activator of neutrophils and a chemotactic agent for lymphocytes. The first

symposium of this series was held at the Royal College of Surgeons of England in December 1988, entitled Novel Neutrophil Stimulating Peptides, and brought together the majority of the laboratories which had published in this area, see *Immunology Today* 10: 146-147(1989). Since the first symposium there has been a dramatic increase in our knowledge of the biology of this family of structurally related peptides. The Second International Symposium on Chemotactic Cytokines was held at the Royal College of Surgeons of England in June 1990. The aim of this symposium was to provide both a forum for discussion and to determine whether this knowledge can be utilised in the design of novel therapeutic strategies for the treatment of inflammatory disorders. Although the majority of studies

have been concerned with the regulation of these peptides at the molecular and cellular level, there is now evidence to suggest that specific members of this superfamily have a role in the pathogenesis of a number of diverse diseases including arthritis, psoriasis, atherosclerosis, wound repair, inflammatory lung diseases and glomerulonephritis.

This report considers the biological and behavioral mechanisms that may underlie the pathogenicity of tobacco smoke. Many Surgeon General's reports have considered research findings on mechanisms in assessing the biological plausibility of associations observed in epidemiologic studies. Mechanisms of disease are important because they may provide

plausibility, which is one of the guideline criteria for assessing evidence on causation. This report specifically reviews the evidence on the potential mechanisms by which smoking causes diseases and considers whether a mechanism is likely to be operative in the production of human disease by tobacco smoke. This evidence is relevant to understanding how smoking causes disease, to identifying those who may be particularly susceptible, and to assessing the potential risks of tobacco products.
